

CS6650 Midterm Mastery

Steps I – III: From HW6 Results to Crash & Recovery

Weifan Li | Distributed Systems | February 2026

Go

ECS Fargate

Terraform

Locust

Circuit Breaker

Agenda

Step I: HW6 Results

Single instance bottleneck → horizontal scaling with ALB

Step II: Key Learnings

CAP, MapReduce, IaC, Parnas, and hands-on scaling

Step III: Crash Demo

Cascading failure with a slow downstream service

Step III: Recovery

Fail Fast + Circuit Breaker + Bulkhead patterns

Step I: Homework 6 Results

Go Product Search Service on ECS Fargate (0.25 vCPU, 512 MB)

Part II: Single Instance

- CPU scaled linearly with concurrency

Memory stayed flat (~11%)

→ CPU-bound workload confirmed

15% CPU

5 Users

46% CPU

50 Users

Part III: ALB + Auto Scaling

- 500 users for 5 minutes

Auto Scaled: 2 → 3 → 4 instances

Zero failures, stable response time

80.7%

CPU Peak

~30s

Recovery

Takeaway: Horizontal scaling with ALB is the correct long-term solution for stateless, compute-bound services.

Step II: What I Found Valuable

CAP & FLP

Partitions are inevitable. The real choice: consistency or availability?

MapReduce

Constrained abstractions enable automatic parallelization and fault tolerance.

Terraform + Docker

From 20 clicks to one command. IaC enables reproducibility at scale.

Parnas (1972)

Information hiding → microservice boundaries. 50-year-old ideas still relevant.

HW6 Scaling

Theory met practice: CPU bottleneck → ALB + Auto Scaling → problem solved.

Failure Models

8 Fallacies, halting/omission/Byzantine failures — vocabulary for real problems.

Step III: Crash & Recovery Architecture

Phase 1: The Crash

No resilience — downstream goes slow (3-8s), everything dies

Metric	Baseline	Under Failure	Impact
RPS	89	4	-95%
Avg Latency	16 ms	4,644 ms	290x
Median	15 ms	5,200 ms	347x
Max	151 ms	8,015 ms	53x

CloudWatch: CPU < 8% — bottleneck is I/O, not CPU

Key Insight: The system didn't return errors — it returned successful responses, just 290x slower. Every goroutine blocked waiting for the slow downstream, creating a silent cascading failure.

```
C:\env> PS C:\Users\N89999\Desktop\CS6658-Distributed-Systems\Midterm\Part 1\crash-recovery> curl "http://crash-recovery-all-1591858157.us-east-2.elb.amazonaws.com/search"

```

resilience_enabled: false, all requests slow but "successful"

Phase 2: The Fix

Three resilience patterns from Sam Newman's Building Microservices

Fail Fast

500ms Timeout

Don't wait 3-8s for a slow service. Time out after 500ms and return fallback data.

Circuit Breaker

5 fails → OPEN

After 5 timeouts, stop calling downstream for 15s. Serve cached fallback instantly.

Bulkhead

Max 10 concurrent

Only 10 goroutines can wait on downstream at once. The rest get fallback immediately.

Result: Same failure conditions (downstream in slow mode), RPS recovered from **4 → 89**. Avg latency from **4,644ms → 18ms**. Zero failures.

One Terraform variable change: `resilience_enabled = false → true`, terraform apply

Full Results Comparison

Requests Per Second

Avg Latency (ms)

```
(.venv) PS C:\Users\98999\Desktop\CS6650-Distributed-Systems\Midterm\Part II\crash-recovery> curl "http://crash-recovery-alb-1591838157.us-west-2.elb.amazonaws.com/metrics"

  "content-length": 323,
  "content-type": "application/json",
  "date": "Sat, 28 Feb 2026 23:47:28 GMT"
}
```

Circuit breaker: CLOSED, fully recovered

Key Takeaways

01 Cascading failures are silent killers

No errors, just 290x slower. Monitor throughput, not just error rates.

02 CPU $\neq$ the bottleneck

CPU was 8% during the crash. I/O wait from blocked goroutines was the real problem.

03 Defense in depth works

Fail Fast + Circuit Breaker + Bulkhead = 100% throughput recovery under identical failure.

04 Degrade gracefully, don't fail hard

Fallback recommendations > 8-second timeouts. Users stay happy.

Thank You
